MultiModal RAG

Different from Traditional RAG i.e. Text In Text Out this takes context from different formats such text image video speech etc

How It Works: The Architectural Shift :

1. Unified Embedding Space
    a. **The Goal:** A picture of a golden retriever and the text string "golden retriever" should have nearly identical vector coordinates.
    b. **Trade-off:** Using separate models for each modality is cheaper to train but often fails to capture the nuances between them. Unified models are more robust but computationally heavier.
2. Multimodal Retrieval
    a. When a user asks a question (which could include an image), the system converts that input into a vector. It then performs a similarity search against a **Vector Database** (like Milvus, Pinecone, or Weaviate) that contains embeddings for text chunks, image frames, or audio transcripts.
3. The Multimodal LLM (MLLM) Synthesis
    a. Once the relevant "context" is retrieved (e.g., three paragraphs of text and two relevant images), it is fed into an MLLM (like **GPT-4o, Gemini 1.5 Pro, or Claude 3.5 Sonnet**).
        i. **Standard RAG:** Only passes text strings to the LLM.
        ii. **Multimodal RAG:** Passes the text strings *and* the raw/encoded visual/audio data into the model's vision/audio encoders.

Implementaion Stratergies

1. **Option A: The "Description-Based" Hack (Low Cost)**
    a. **Flow:** Use a small vision model (like LLaVA) to caption every image in your database → Store captions in a standard text vector DB.
    b. **Pros:** Very cheap; uses existing text-RAG infrastructure.
    c. **Cons:** Lossy. A caption like "a graph showing sales" misses the specific data points needed for deep analysis.
2. **Option B: Native Multimodal (Stable & Precise)**
    a. **Flow:** Use a Multi-Vector Retriever. Store the raw images/videos in a blob store (S3/GCS) and their high-dimensional embeddings in a vector DB.
    b. **Pros:** High fidelity; allows the LLM to perform its own reasoning on the visual data.
    c. **Cons:** Higher storage costs and requires an MLLM with a large context window.

Real-World Trade-offs

1. Latency: Encoding images on the fly during retrieval adds milliseconds. If you're building a real-time assistant, you'll

need optimized inference kernels.

2. Cost: Processing tokens for images is significantly more expensive than text. For example, a single high-res image can count as 1,000+ tokens.

How to counter the Tradeoff

The biggest trade-off in Multimodal RAG is **High Cost/Latency** vs. **Precision**. To solve this, we use a **"Tiered Retrieval"** architecture.

The Strategy: Multiphase Ranking

1. **Phase 1: Lightweight Filter (The "Sieve")**
    a. Use a cheap, fast encoder (like a small CLIP variant) to narrow 1,000,000 assets down to the top 100.
2. **Phase 2: Reranking (The "Magnifying Glass")**
    a. Take those 100 assets and run a more expensive "cross-encoder" or a smaller MLLM (like LLaVA) to score them for actual relevance to the query.
3. **Phase 3: Final Synthesis**
    a. Pass only the top 3–5 *highly relevant* assets to the expensive MLLM (GPT-4o/Gemini) for the final answer.

Benefit: You get the precision of the most expensive models without paying for them to "read" every single document in your database.

Making it "Production Ready"

To move from a notebook to a stable enterprise service, you need three "pillars":

1. The Ingestion Pipeline (Asynchronous & Fault-Tolerant)
    a. Don't process images in the main request flow. Use a **Message Queue** (like RabbitMQ or Kafka).
    b. When a PDF is uploaded, worker nodes extract images, tables, and text separately.
    c. **Content Hashing:** Before embedding, hash the file. If the file hasn't changed, skip the expensive GPU embedding step and reuse the old vector.
2. Semantic Caching
    a. Store common queries and their multimodal results in a cache (like Redis). If a user asks a similar question, serve the cached answer. This can reduce LLM costs by **30–50%**.
3. Evaluation (The "Vibe Check" is not enough)
    a. You need automated metrics:
    b. **Context Adherence:** Does the answer actually use the retrieved image?

Evaluation Methods

The RAG Triad (Component-Level Metrics)

This is the standard for RAG, but we must adapt it for **multimodal** inputs.

1. Contextual Relevance (Retriever)
    a. **What it checks:** Did the system pull the right images and text?
    b. **Metrics:** * **Precision@K:** If we retrieve 5 items, how many are actually useful?
        i. **Recall@K:** Did we miss the critical "golden" image that holds the answer?
        ii. **MRR (Mean Reciprocal Rank):** Is the most relevant image at the very top, or buried at position #10?
2. Faithfulness / Groundedness (Generator)
    a. **What it checks:** Did the model hallucinate?
    b. **Multimodal Check:** Does the answer match the visual evidence?
    c. **Evaluation Method:** Use **LLM-as-a-Judge** (e.g., GPT-4o or Gemini 1.5 Pro). We provide the judge with the retrieved image and the generated answer, asking: *"Does this answer cite specific visual features found in the image?"*
3. Answer Relevance (Prompt/Instruction Following)
    a. **What it checks:** Does the answer actually address the user's specific question?
    b. **Metrics:** Semantic similarity (using BERTScore or Cosine Similarity) between the generated answer and a human "Golden Answer."

Multimodal-Specific Performance Metrics

Standard text metrics aren't enough when you have images and videos.

1. Visual Grounding Accuracy
    a. We check if the model can "point" to where it found the information.
    b. **Bounding Box Evaluation:** If the system says "The pipe is leaking at the joint," we evaluate if it can correctly identify the (x, y) coordinates of that joint in the retrieved image.
2. OCR & Document Extraction Fidelity
    a. If your RAG handles PDFs/Charts:
    b. **CER (Character Error Rate):** How accurately did our vision model read the text inside the charts?
    c. **Table Extraction Score:** Did it maintain the structure of the data, or did it scramble the rows/columns?

Production & Operational Metrics

To be "Production Ready," the system must be fast, cost-effective, and safe.

Metric	What it measures	Goal for "Best" System
P99 Latency	Time to respond for 99% of users.	< 2 seconds for complex

		multimodal queries.
Token Efficiency	Cost per query.	Minimize high-res image tokens using **Dynamic Tiling**.
Safety/Guardrails	Rejection of harmful or off-topic visual content.	0% leakage of sensitive visual data.
Drift Detection	Does performance drop as we add more images?	Stable accuracy regardless of database size.

The "Gold Standard" Benchmarks (Theory vs. Reality)

To claim the system is "best in theory," we should benchmark it against established datasets:

1. **MMMU (Massive Multi-discipline Multimodal Understanding):** Tests college-level reasoning across fields like art, science, and engineering.
2. **T^2-RAGBench:** Specifically designed for RAG systems handling text + tables (critical for business).
3. **MRAG-Bench:** Focuses on vision-centric RAG where the answer *only* exists in the visual data, not the text.

Architectural Strategy for Best Evaluation

To make this automated and scalable:

1. **Synthetic Data Generation:** Use a high-end MLLM to generate 1,000 "Question-Image-Answer" pairs from your own private data. This creates a "Golden Dataset" for your specific use case.
2. **A/B Testing Framework:** Before deploying a new embedding model or prompt, run it through the "LLM-as-a-Judge" pipeline to see if the Faithfulness score improves.

System Architecture

RAG Tech Stack

1. Ingestion & Orchestration: The "Nervous System"

- **Selected Tech: Apache Kafka** + **LlamaIndex**
- **Why Kafka over RabbitMQ?** Multimodal data (videos/HD images) is heavy. Kafka's **log-based architecture** and **zero-copy** transfer handle massive throughput better than RabbitMQ's exchange-based routing. Crucially, Kafka allows "replayability" if our embedding model changes, we can re-process all historical images easily.

- **Why LlamaIndex over LangChain?** LlamaIndex is fundamentally built for **data indexing**. While LangChain is great for complex "agent" logic, LlamaIndex offers superior native support for hierarchical document structures and multimodal metadata, which is critical for PDF-to-Image-to-Vector workflows.

2. Retrieval & Embedding: The "Memory Bank"

- **Selected Tech: Milvus** (Vector DB) + **ColPali** (Retriever)
- **Why Milvus over Pinecone? Milvus** offers a "Hybrid Search" engine (scalar + vector) that is highly cost-effective when self-hosted on Kubernetes. It supports **multi-vector indexing**, which is necessary for storing multiple embeddings per document (e.g., one for text, one for images).
- **Why ColPali over CLIP?** CLIP provides a single "vibe" vector for an image. **ColPali (ColBERT-style)** creates token-level late interactions.
  - **Benefit:** It can "read" the text inside a chart or table natively without needing an error-prone OCR (Optical Character Recognition) step.

3. Synthesis: The "Brain"

- **Selected Tech: Gemini 1.5 Pro / Flash**
- **Why Gemini?** In 2026, Gemini's **2-million token context window** is the architect's "get out of jail free" card.
  - **The Advantage:** Traditional RAG is forced to cut data into tiny chunks. Gemini allows you to retrieve **entire high-res PDF pages or 10-minute video clips** and feed them raw into the prompt. This drastically reduces "Context Fragmentation" where the model misses the big picture.

How to Make it "Production Ready" (The "Stable" Layer)

To satisfy the **Senior Architect** requirement of stability and cost-effectiveness:

1. **Tiered Embedding (Cost Saver):** Use **Matryoshka Embeddings**. This allows us to store vectors that can be "truncated." We store a 2560-dim vector but only search using the first 768 dimensions for 90% of queries. If the match score is low, we "re-rank" using the full vector.
2. **Dead Letter Queues (Stability):** Multimodal processing fails often (corrupt images, unsupported video codecs). In Kafka, we route failed files to a **Dead Letter Queue (DLQ)** for manual inspection or retries, ensuring the main pipeline never stalls.
3. **Semantic Firewall:** Implement a "Guardrail" layer (using a tool like NeMo Guardrails) before the LLM. It checks if the retrieved image contains PII (Personally Identifiable Information) or sensitive data before the "Brain" ever sees it.

Architectural TradeOff and Advantages

Tech Block	Chosen Tech	Key Advantage	The "Architect's" Trade-off
Ingestion	Kafka	Extreme durability & high throughput.	**Complexity:** Requires Zookeeper/KRaft management and higher

			dev-ops overhead.
Retrieval	ColPali	State-of-the-art precision for visual documents.	**Storage Cost:** Generates more vectors than standard CLIP, increasing DB costs by ~3x.
Database	Milvus	Horizontal scalability (billions of vectors).	**Latency:** Initial setup is "heavy." Not ideal for tiny projects.
LLM	Gemini 1.5	Massive context; native multimodal reasoning.	**Cost:** Large context usage is expensive. Needs a "Semantic Cache" to be sustainable.

Finalized Production Tech Stack

1. Ingestion & Pipeline
    a. **Orchestration:** LlamaIndex
    b. **Message Broker:** Apache Kafka
    c. **Processing Workers:** Celery + Redis
2. Storage & Retrieval
    a. **Vector Database:** Milvus (on Kubernetes)
    b. **Primary Embedding Model:** SigLIP (Vision) + `all-MiniLM-L6-v2` (Text)
    c. **Secondary Metadata:** PaddleOCR (for visual text extraction)
    d. **Blob Storage:** MinIO or S3 (Raw Assets)
3. Synthesis & Evaluation
    a. **Core MLLM:** Gemini 1.5 Pro
    b. **Inference Engine:** vLLM
    c. **Evaluation Framework:** Ragas (using GPT-4o as Judge)
    d. **Semantic Cache:** Redis
4. Monitoring & Guardrails
    a. **Observability:** Prometheus + Grafana
    b. **Safety Layer:** NeMo Guardrails
    c. **Tracing:** Arize Phoenix
